WHERE INTENT BECOMES EXECUTION, INTELLIGENTLY

ArcFlow.ai

The AI-Native Workflow Engine for Modern Teams.

The Workflow Paradox

Automation got faster. Orchestration didn't.

15–20

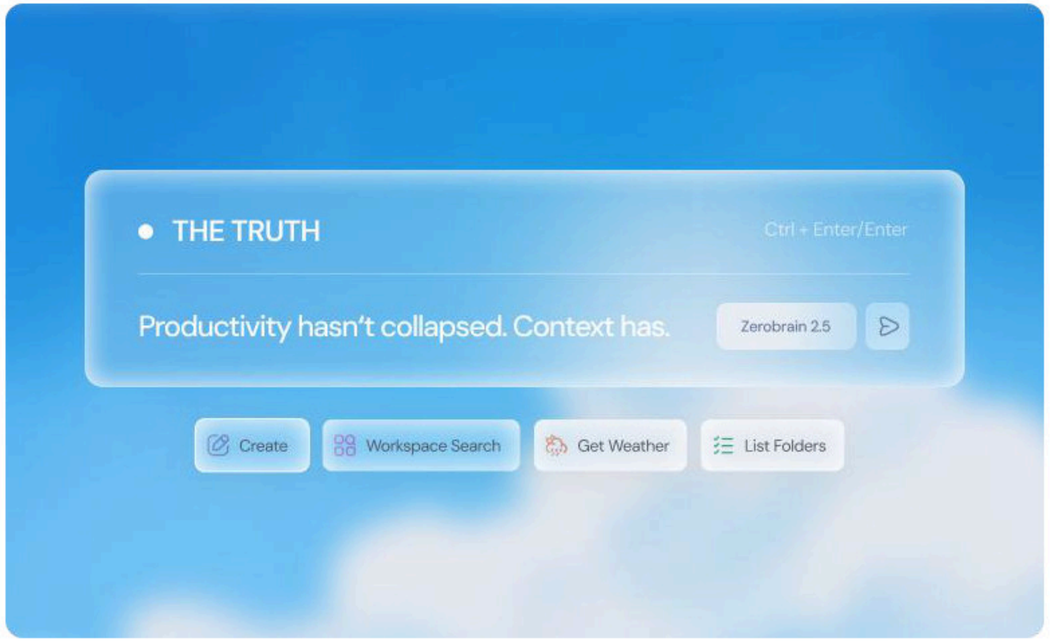

Pipelines per Team

Active automated workflows managed by typical eng teams

200+

Enterprise Pipelines

Average workflow count across organizations at scale

The average engineering team now manages 15 to 20 automated pipelines across CI/CD, data, and ML workflows. For enterprises, that number exceeds 200, each with its own triggers, failure modes, and dependencies.

Workflows break silently across disconnected systems. Failures cascade without context. Teams spend more time debugging orchestration than building products, and critical handoffs fall through the cracks.

The Hidden Cost of Broken Workflows

THE REAL COST EQUATION

Orchestration is cheap to build and expensive to fix.

Downtime

Up to 35% of engineering time is lost to incident response, debugging cascading failures across pipelines that lack centralized observability or dependency tracking.

Wasted Compute

$8–15M annually burned on redundant pipeline runs, zombie jobs, and over-provisioned infrastructure that silently drain budgets.

Missed SLAs

Late deliveries delay launches, degrade customer trust, and compound when teams operate with incomplete context about upstream dependencies.

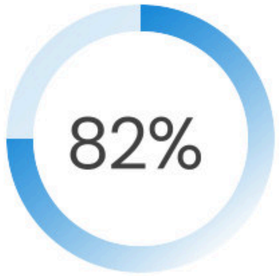

THE AUTOMATION PARADOX

Why Existing Tools Fall Short

Adoption is High. Reliability is Not.

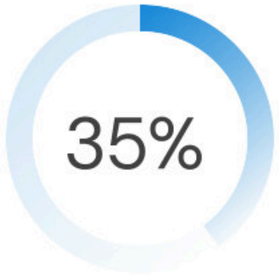

The data reveals a striking disconnect: while workflow tools have achieved widespread adoption, they have failed to deliver the orchestration reliability that modern engineering demands.

Automation executes tasks efficiently. But it does not own outcomes, maintain accountability, or build institutional resilience.

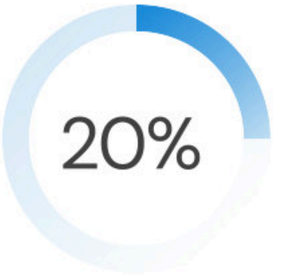

Adoption

Teams using workflow automation

Trust Level

Trust automation for critical paths

Governance

Organizations with rollback policies

Most workflow tools are wrappers, not systems

Impressive pipeline demos that deliver fragile operations. Automation that impresses in staging but fails when teams depend on it in production under real-world conditions.

What They Can Do

- Trigger jobs on schedule or event
- Chain steps in a DAG
- Retry failed tasks with backoff
- Visualize pipeline status

What They Cannot Do

- Own workflows end-to-end across services
- Track decisions and their downstream impact
- Self-heal when dependencies shift
- Act as a system of record for operations

ArcFlow Intelligent Pipeline Search

What Makes ArcFlow Search Operations-Grade.

ARCFLOW SEARCH IS DIFFERENT

Context-Aware { 01 }

- Understands relationships between services, teams, and timelines
- Search across pipelines, deployments, incidents, logs, and decisions

Permission-Aware { 02 }

- No data leakage. No over-retrieval.
- Every result respects RBAC, namespace boundaries, and access policies

Source-Cited by Default { 03 }

- Teams can verify, trust, and act — not guess
- Every answer links back to the exact run, commit, or config change

Actionable { 04 }

- Search does not end with answers — it drives resolution
- Turn search results into rollbacks, retriggers, approvals, or escalations

Who ArcFlow Is Built For

One platform, across stages.

STARTUP

Early-stage teams overwhelmed by pipeline proliferation, needing structure without overhead

TEAM

Growing teams requiring shared orchestration and coordination as they scale

BUSINESS

Revenue and operations teams demanding accuracy, traceability, and reliable execution

ENTERPRISE

Platform and SRE teams needing comprehensive visibility, governance, and security controls

CONTROL BEATS FEATURES

Why ArcFlow Wins

Other Tools

- Solve isolated, specific problems
- Depend on brittle integrations that break
- Produce outputs without accountability

ArcFlow

- Owns the complete workflow from trigger to resolution
- Connects decisions directly to execution and outcomes
- Becomes the system of record for operational intelligence
